

GlassBench alpha-anchor rescue protocol

A higher-k Fs measurement is separated from event-clock and held-out prediction gates.

target	rescue stage	post-rescue claim boundary
KA2D T=0.23	alpha anchor rescue design ready real event cloc	required k=2.7; k/kmax=1.69; anchor measurement=1; design=1; blocker=physical_time_semantics post-rescue alpha consistent=1; event clock=0; closed loop=0 remaining=physical time semantics;macro heldout observables;threshold sweep event cl
KA2D T=0.30	alpha anchor rescue upstream incomplete	required k=0; k/kmax=0; anchor measurement=0; design=0; blocker=sparse_time_code_coverage post-rescue alpha consistent=0; event clock=0; closed loop=0 remaining=physical time semantics;macro heldout observables;threshold sweep event cl

Resolving the alpha-anchor k-grid gap does not by itself establish a persistence/exchange event-clock inversion.
