

GlassBench interval-censored first-crossing clock

Sparse-lag crossings are converted into lower/upper clock bounds, not a full persistence/exchange inversion.

target	interval-clock stage	first-crossing clock bounds
KA2D T=0.23	interval censored persistence clock candidate	structure=151; crossed=0.24; right-censored=0.76; ready=1 mean interval=[1.3e+05, 1.37e+06], midpoint=7.5e+05, width=1.24e+06 blocker=interval_censoring_and_replica_id; next=fit_interval_censored_persistence_distribu
KA2D T=0.30	interval clock sparse lag upstream incomplete	structure=3; crossed=0; right-censored=0; ready=0 mean interval=[0, 0], midpoint=0, width=0 blocker=sparse_lag_event_clock; next=complete_sparse_lag_event_clock_audit
KA2D T=0.30	interval clock sparse lag upstream incomplete	structure=none; crossed=0; right-censored=0; ready=0 mean interval=[0, 0], midpoint=0, width=0 blocker=sparse_lag_event_clock; next=complete_sparse_lag_event_clock_audit

The result is a quantitative persistence-clock bound with right censoring and interval censoring explicitly retained.
