

# GlassBench direct-alpha multi-lag crossing canary

The cached lag ladder supplies a threshold-crossing target, not a persistence/exchange event clock.

| target      | crossing canary stage                            | multi-lag threshold crossing status                                                                                                                                                                                    |
|-------------|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KA2D T=0.23 | multilag displacement crossing canary ready repl | structure=151; samples=25800; ever crossed=0.24; never=0.76<br>recross=0.236; first-cross q/q_max=3.44; axis0 replica=1<br>blocker=frame_axis_is_isoconfigurational_r; next=extract_true_particle_time_trajectory_for_ |
| KA2D T=0.30 | pe feasibility bound upstream incomplete         | structure=none; samples=0; ever crossed=0; never=0<br>recross=0; first-cross q/q_max=0; axis0 replica=0<br>blocker=pe_feasibility_bound; next=complete_direct_alpha_pe_feasibility_bound                               |

Crossings along cached lag outputs define a segmentation target; true PE inversion still requires particle time trajectories.
