

# GlassBench interval-censored persistence fit

A one-parameter censored exponential survival law estimates tau\_p while leaving exchange-clock blockers explicit.

| target      | fit stage                                          | censored persistence-law estimate                                                                                                                                                                                                                |

| KA2D T=0.30 | interval censored persistence fit upstream incompl | structure=none; rate=0; mean tau_p=0; tau_p/tau_alpha=0<br>crossed observed=0; exponential predicted=0; latest lag=0<br>blocker=interval_censored_clock; next=complete_interval_censored_first_crossing_                                         |

The fitted persistence scale is a censored-clock estimate; exchange statistics and replica identity are still required for real PE inversion.
