

Low-temperature waiting-law and shuffle diagnostic

T=0.45; p_hop uses fixed 5+5 windows and thresholds 0.16-0.24.

A. Nominal-threshold jump-count Fano

B. Threshold-stable decomposition

Empirical iid predicts single-particle count fluctuations; sequence memory and persistent particle rates are secondary.
Collective event-count covariance remains 15-37x, while this p_hop clock explains less than half of held-out diffusion.
